Lecture 5 : Matrices and Matrix Operations

Agenda:

- 1. Matrix Multiplication
- 2. Examples of Matrix Multiplication

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

3. Other Matrix Operations

Matrices

Recall

Definition

An $n \times m$ matrix is a rectangular arrangement of nm real numbers with n rows and m columns.

The usual way we will indicate a generic $n \times m$ matrix:

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \ddots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix}$$

Here a_{ij} is the entry in the i^{th} row (reading left to right) and j^{th} column (reading top to bottom).

Matrix Multiplication

• Suppose **A** is a matrix with *m* columns and **B** is a matrix with *m* rows. Then the matrix product **AB** is defined. If **A** is an $n \times m$ matrix and **B** is an $m \times p$ matrix, the matrix product **AB** is the $n \times p$ matrix with entries

$$\left(\mathbf{AB}\right)_{ij} = Row_i\left(\mathbf{A}\right) \cdot Col_j\left(\mathbf{B}\right)$$

• If the number of columns of the first factor matrix **A** is not the same as the number of rows of the second factor matrix **B**, then the product **AB** is **undefined**.)

• the matrix dimensions follow the rule

$$(n \times m) \cdot (m \times p) \longrightarrow (n \times p)$$

Examples of Matrix Multiplication

Example

$$\begin{bmatrix} 1\\2\\3 \end{bmatrix} \begin{bmatrix} 1&-1\\2&-1\\1&-2 \end{bmatrix}$$
 is undefined

since

$$(3 \times 1)(3 \times 2) \longrightarrow$$
 undefined matrix product
 $\uparrow \uparrow$
mismatch

(matrix multiplication requires the number of columns in the first factor to equal the number of rows in the second factor)

Example: Multiplying a Vector by Matrix

If $\mathbf{a} \equiv (a_1, \dots, a_n) \in \mathbb{R}^n$ is an ordered list of *n* numbers, there are two different ways of interpreting **A** as a matrix

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Example: Multiplying a Vector by Matrix, Example

$$\left[\begin{array}{cc} 1 & 2 \\ -1 & 2 \end{array} \right] \left[\begin{array}{c} 1 \\ -1 \end{array} \right]$$
 is defined

since for this product we have

$$(2 \times 2)(2 \times 1) \longrightarrow (2 \times 1)$$

 $\uparrow \uparrow$
match

Explicitly computing the product:

$$\begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 1 \\ -1 \end{bmatrix} = \begin{bmatrix} (1,2) \cdot (1,-1) \\ (-1,2) \cdot (1,-1) \end{bmatrix}$$
$$= \begin{bmatrix} (1)(1) + (2)(-1) \\ (-1)(1) + (2)(-1) \end{bmatrix}$$
$$= \begin{bmatrix} -1 \\ -3 \end{bmatrix}$$

On the other hand,

$$\begin{bmatrix} 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} = [(1, -1) \cdot (1, -1) \quad (1, -1) \cdot (2, 2)]$$
$$= \begin{bmatrix} (1)(1) + (-1)(-1) \quad (1)(2) + (-1)(2) \end{bmatrix}$$
$$= \begin{bmatrix} 2 & 0 \end{bmatrix}$$

Comparing these two results

$$\begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 1 \\ -1 \end{bmatrix} = \begin{bmatrix} -1 \\ -3 \end{bmatrix}$$
$$\begin{bmatrix} 1 & -1 \end{bmatrix} \begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} = \begin{bmatrix} 2 & 0 \end{bmatrix}$$

So even though the 2×1 matrix $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$ and the 1×2 matrix $\begin{bmatrix} 1 & -1 \end{bmatrix}$ correspond to the same 2-dimensional vector (1, -1), their products with the 2×2 matrix $\begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix}$ are not the same.

Example

Let
$$\mathbf{A} = \begin{bmatrix} 2 & 1 \\ -1 & 1 \end{bmatrix}$$
 and $\mathbf{B} = \begin{bmatrix} 1 & -1 \\ -1 & 2 \end{bmatrix}$.
 $\mathbf{AB} = \begin{bmatrix} 2 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ -1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ -2 & 3 \end{bmatrix}$
 $\mathbf{BA} = \begin{bmatrix} 1 & -1 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ -1 & 1 \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ -4 & 1 \end{bmatrix}$
So
 $\mathbf{AB} \neq \mathbf{BA}$

Thus, if the order of factors changes the value of a product of matrices can also change.

Indeed, it can happen that a product **AB** exists but **BA** is not even defined:

If **A** is an $n \times m$ matrix and **B** is a $m \times p$ matrix, then

$$\mathbf{AB} \quad \sim \quad (n \times m)(m \times p) \quad \longrightarrow \quad (n \times p)$$

so the product **AB** is defined and it will be a $n \times p$ matrix. On the other hand,

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

Moral: One must always maintain the order of factors when multiplying matrices.

Another deviation from the ordinary multiplication of numbers

Recall that for real numbers xy = 0 implies either x = 0 or y = 0. Now consider

$$\left[\begin{array}{rrr} -1 & 1 \\ 0 & 0 \end{array}\right] \left[\begin{array}{rrr} 1 & 1 \\ 1 & 1 \end{array}\right] = \left[\begin{array}{rrr} 0 & 0 \\ 0 & 0 \end{array}\right]$$

This example shows that for matrices, it can happen that AB = 0 with neither A or B equal to the zero matrix 0.

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬる

The Identity Matrix

Consider the following matrix products

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} a_{11} & 0 & 0 \\ 0 & 1 & 0 \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

And so multiplying any 3×3 matrix **A** by the matrix

$$\mathbf{I} = \left[\begin{array}{rrr} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right]$$

just replicates the matrix A:

$$\mathbf{AI} = \mathbf{IA} = \mathbf{A}$$

The Identity Matrix, Cont'd

The preceding example generalizes to arbitrary $n \times n$ matrices (usually called "square matrices") and motivates the following definition.

Definition

The $n \times n$ **Identity matrix** is the the $n \times n$ matrix **I** whose entries are given by

$$I_{ij} = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases} \iff \mathbf{I} = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & 0 & \vdots \\ \vdots & \ddots & \\ 0 & 0 & \cdots & 1 \end{bmatrix}$$

In other words, **I** is the $n \times n$ matrix with 1's along the diagonal (running from the upper left to the lower right) and 0's everywhere else.

The Identity Matrix, Cont'd

The identity matrix $\boldsymbol{\mathsf{I}}$ has the property that

AI = A whenever AI is defined IA = A whenever IA is defined

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三三 - のへぐ

Addition and Scalar Multiplication of Matrices

Definition

Suppose **A** and **B** are both $n \times m$ matrices. Then the **matrix sum A** + **B** is defined as the $n \times m$ matrix with entries

$$(\mathbf{A} + \mathbf{B})_{ij} = A_{ij} + B_{ij}$$

Definition

Let $\lambda \in \mathbb{R}$, and let **A** be an $n \times m$ matrix. Then the scalar product of **A** by λ is the $n \times m$ matrix λ **A** with entries

$$(\lambda \mathbf{A})_{ij} = \lambda A_{ij}$$

Example

Let

$$\mathbf{A} = \begin{bmatrix} 1 & -1 & 2 \\ 1 & 0 & 1 \end{bmatrix} \quad , \quad \mathbf{B} = \begin{bmatrix} 0 & 1 & -1 \\ 2 & 1 & 0 \end{bmatrix}$$

Then

$$\mathbf{A} + \mathbf{B} = \begin{bmatrix} 1+0 & -1+1 & 2-1 \\ 1+2 & 0+1 & 1+0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1 \\ 3 & 1 & 1 \end{bmatrix}$$
$$3\mathbf{A} = \begin{bmatrix} (3)(1) & (3)(-1) & (3)(2) \\ (3)(1) & (3)(0) & (3)(1) \end{bmatrix} = \begin{bmatrix} 3 & -3 & 6 \\ 3 & 0 & 3 \end{bmatrix}$$

(ロ)、(型)、(E)、(E)、 E) の(()

The Transpose of a Matrix

Definition

Suppose **A** is an $n \times m$ matrix. The **transpose** of **A** is the $m \times n$ matrix **A**^t with entries

$$\left(\mathbf{A}^{t}
ight)_{ij}=A_{ji}$$
 ; for $i=1,\ldots,m$ $j=1,\ldots,n$

(note how the row and column indices have been reversed). Equivalently, \mathbf{A}^t is the matrix obtained from \mathbf{A} by converting, in order, the rows of \mathbf{A} into columns.

Example

lf

$$\mathbf{A} = \begin{bmatrix} 1 & 3 \\ -2 & 1 \\ 3 & -1 \end{bmatrix}$$
$$\mathbf{A}^{t} = \begin{bmatrix} 1 & -2 & 3 \\ 3 & 1 & -1 \end{bmatrix}$$

then

Remarks

If A is an n × m matrix then A² = AA is defined only if m = n. However, the products AA^t and A^tA are always well-defined.

If v is a column vector (i.e., an n×1 matrix), then v^t is a row vector (i.e., a 1×n matrix) and

$$\mathbf{v}^{t} \mathbf{v} = [v_{1} \ v_{2} \ \cdots \ v_{n}] \begin{bmatrix} v_{1} \\ v_{2} \\ \vdots \\ v_{n} \end{bmatrix}$$
$$= [(v_{1})^{2} + (v_{2})^{2} + \cdots + (v_{n})^{2}] = [\|\mathbf{v}\|^{2}]$$

Remarks, Cont'd

A square matrix is a matrix with the same number of rows as it has columns.

• A square matrix **A** is called **symmetric** if $\mathbf{A}^t = \mathbf{A}$. **Example:**

$$\begin{bmatrix} 2 & 1 & -1 \\ 1 & 3 & 2 \\ -1 & 2 & 1 \end{bmatrix}$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

is a symmetric matrix.

Properties of the Transpose Operation

Theorem

Let **A** and **B** be matrices and let $\lambda \in \mathbb{R}$.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 ○のへ⊙

Back to Linear Systems

Recall matrices were introduced as a means of writing large systems as linear equations as a single matrix equation.

$$\begin{array}{ccc} a_{11}x_1 + & \cdots & +a_{1m}x_m = b_1 \\ \vdots & & \vdots \\ a_{n1}x_1 + & \cdots & +a_{nm}x_m = b_n \end{array} \right\} \qquad \Longleftrightarrow \qquad \mathbf{A}\mathbf{x} = \mathbf{b}$$

where

$$\mathbf{A} = \begin{bmatrix} a_{11} & \cdots & a_{1m} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nm} \end{bmatrix} \quad , \quad \mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix} \quad , \quad \mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_n \end{bmatrix}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへ⊙

Case 0: 0 equations in m unknowns

In this case, there are no conditions placed on the variables x_1, \ldots, x_m ; and so each variable is allowed to range over the entire real line. The "solution vectors" are just

$$\left\{ \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_m \end{bmatrix} \mid x_1, x_2, \dots, x_m \in \mathbb{R} \right\} = \mathbb{R}^m$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

Case 1: 1 equation in m unknowns

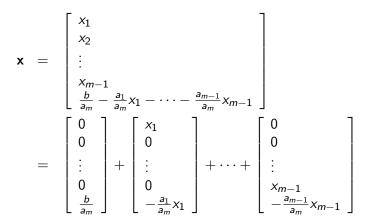

We now impose a single linear equation

$$a_1x_1+a_2x_2+\cdots+a_mx_m=b$$

on *m* variables x_1, \ldots, x_m . So long as $a_m \neq 0$ (so that the term $a_m x_m$ actually contributes to the equation), this equation is readily solved for x_m :

$$x_m = \frac{b}{a_m} - \frac{a_1}{a_m} x_1 - \dots - \frac{a_{m-1}}{a_m} x_{m-1}$$

Thus, a solution vector will be a vector of the form

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

or

$$\mathbf{x} = \begin{bmatrix} 0\\0\\\vdots\\0\\\frac{b}{a_m} \end{bmatrix} + x_1 \begin{bmatrix} 1\\0\\\vdots\\0\\-\frac{a_1}{a_m} \end{bmatrix} + \dots + x_{m-1} \begin{bmatrix} 0\\0\\\vdots\\1\\-\frac{a_{m-1}}{a_m} \end{bmatrix}$$

Note how in this last form, the solution vector is expressed as a point on a (m-1)-dimensional hyperplane of vectors; i.e., a set of vectors of the form

$$\{\mathbf{p}_0+t_1\mathbf{d}_1+\cdots+t_{m-1}\mathbf{d}_{m-1}\mid t_1,\ldots,t_{m-1}\in\mathbb{R}\}$$

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬる

We have seen that the solution space of a linear equation in m variables is a (m-1)-dimensional hyperplane in the vector space of variable values.

Thus, to satisfy a two linear equations in m variables, a point **x** must lie on both of the corresponding hyperplanes.

Satisfying multiple equations means that solution points live on multiple hyperplanes.

Geometric Construction of Solutions, Cont'd

Let Eq_1, \ldots, Eq_n be a system of *n* linear equations in *m* unknowns. and let $\mathcal{H}_1, \ldots, \mathcal{H}_n$ be the corresponding hyperplanes

$$\mathcal{H}_i =$$
solution set of Eq_i , $i = 1, \ldots, n$

Then a point in the solution set of a linear system must simultaneously live on each hyperplane H_i . Thus, geometrically,

solution set
$$= \bigcap_{i=1}^{n} \mathcal{H}_i$$

i.e., a point in the solution set must lie in the intersection of all the equation-hyperplanes.

Solving Systems of Linear Equations
